Femoral triangle block plus iPACK block versus local infiltration analgesia for anterior cruciate ligament reconstruction: an infographic

Eric S Schwenk (1),¹ Rajnish K Gupta 💿

ABSTRACT

Anterior cruciate ligament reconstruction can be painful, and both the femoral triangle block and local infiltration analgesia have been shown to provide effective analgesia after this surgery. A relatively new block, the iPACK (infiltration between the popliteal artery and the capsule of the knee), has been reported to provide posterior knee analgesia. In this triple-blinded, randomized controlled trial of 60 patients, the combination of femoral triangle block and iPACK block reduced opioid consumption for 24 hours postoperatively compared with local infiltration analgesia.¹ However, other pain and functional outcomes were the same in both groups.
