Conclusions Although SBYB is performed routinely, we found scope to improve documentation and ensure better adherence to national guidance. Following departmental teaching, we placed SBYB posters throughout, created specific RA procedure trays, and created reminders on our online documentation. These changes were reflected in our locally created protocol. Currently, we seek to improve SSM through liaison with our surgical colleagues, and increasing the vigilance of theatre staff undertaking appropriate checks.

Background and Aims Aspiration accounts for 50% of anaesthesia related deaths. Inadequate pre-operative risk assessment is one of the contributing factors. Point-of-care gastric ultrasound (POC-USG) is a novel but valid diagnostic tool to quantify gastric volume (GV) and ascertain risk of aspiration.

The aims of our project were to determine, in fasted patients undergoing emergency surgery:

- if quantitative and qualitative methods of assessment of gastric volume (GV) correlate with each other
- if GV assessment identifies at high risk of aspiration, and
- if higher risk of aspiration was identified, whether this changed the plan for airway management

Methods Patients booked onto the emergency list were prospectively scanned using low frequency 1–5MHz curvilinear transducer. GV was estimated by inputting cross sectional area of the antrum in the right lateral decubitus position (RLD-CSA) into a validated model. This was compared to acceptable GV determined by the patient’s weight (low risk for aspiration = <1.5ml kg⁻¹; high risk >1.5ml kg⁻¹). Qualitative assessment was categorised as grade 0–2 based on antrum appearance. Risk was communicated to the anaesthetist and assessment was categorised as grade 0–2 based on antrum appearance. Risk was communicated to the anaesthetist and the final airway plan recorded.

Results There was 100% (n=15) correlation between quantitative and qualitative methods. 3 were identified at high risk of aspiration (GV >1.5ml kg⁻¹). All these patients were fasted >6h. 2 had a change in airway plan and 1 patient was undergoing a regional technique.

Conclusions Fasting >6h does not always preclude a high risk of aspiration. POC-USG can aid decision-making as part of a multi-modal assessment of aspiration risk to improve patient safety. Ethics approval not required.

Background and Aims After surgical correction of proximal femoral fractures or total hip arthroplasty severe pain scores are expected. Insufficient pain control in the postoperative period compromises recovery and increases the risk of developing chronic pain. Pericapsular nerve group (PENG) block, described in 2018, is an interfascial plane block that targets the articular branches of the femoral, obturator, and accessory obturator nerves. Blocked branches convey nociceptive information, preserving motor function and, as such, early ambulation and active collaboration in rehabilitation programs are favored. This study aims to compare the analgesia provided by PENG block with that obtained by performing femoral nerve block or iliac fascia block.

Methods A retrospective study was performed including patients from 2018 to 2022 who underwent total hip arthroplasty or surgical correction of traumatic proximal femoral fractures. The effectiveness of PENG block, iliac fascia block and femoral nerve block was compared by using pain scores and requirement of rescue analgesia. This work was approved by the ethic committee.

Results A total of 479 patients were enrolled for this study. Comparing the different techniques of locoregional analgesia performed, no differences were found.

Conclusions The PENG block appears to be an easy-to-perform technique with the benefit of preserving motor function associated with adequate control of postoperative pain, allowing adherence to early rehabilitation programs, reducing the risk of falls and patient satisfaction.

**CUMULATIVE RADIATION DOSE EXPOSURE IN FLUOROSCOPY-GUIDED EPIDURAL INTERLAMINAR LUMBAR STEROID INJECTIONS**

V Drabijeva*, J Logina, 5 Petronis. 1Rigas 2nd Hospital, Riga, Latvia; 2Riga Stradins University, Riga, Latvia

10.1136/rapm-2022-ESRA.S.544

**Background and Aims** Fluoroscopy-guided epidural interlaminar steroid injections (FEISI) widely used for managing low back pain (LBP). There is lack of data on cumulative radiation dose (CRD) in patients receiving more than one FEISI (1).

- it is very important to determine CRD for three consecutive FEISI and to define factors that correlate with higher dose area product (DAP) or prolong fluoroscopy time (FT).

**Methods** A retrospective study was performed including patients from 2018 to 2022 who underwent total hip arthroplasty or surgical correction of traumatic proximal femoral fractures. The effectiveness of PENG block, iliac fascia block and femoral nerve block was compared by using pain scores and requirement of rescue analgesia. This work was approved by the ethic committee.

**Results** A total of 479 patients were enrolled for this study. Comparing the different techniques of locoregional analgesia performed, no differences were found.

**Conclusions** The PENG block appears to be an easy-to-perform technique with the benefit of preserving motor function associated with adequate control of postoperative pain, allowing adherence to early rehabilitation programs, reducing the risk of falls and patient satisfaction.
Background and Aims Rectus sheath block (RSB) is a regional anesthesia technique, that provides somatic analgesia (without visceral analgesia) by blocking the ventral rami of the 7th to 12th intercostal nerves with injection of local anesthetic in the space between the rectus abdominis muscle and the posterior aspect of the 7th intercostal nerves with injection of local anesthetic in the space between the rectus abdominis muscle and the posterior aspect of the 7th intercostal nerves. It can be used as a part of multimodal analgesia together with usage of non-opioid drugs, such as lidocaine, ketamine and magnesium, given as a continuous intravenous infusion together with usage of non-opioid drugs, such as lidocaine, ketamine and magnesium, given as a continuous intravenous infusion.

Results During surgery request for opioids was lower and pain scores in the first 72 hours after surgery were reduced too. Conclusions Bilateral rectus sheath block with continuous intravenous infusion of lidocaine, ketamine and magnesium provides sufficient analgesia during emergency laparotomies, lower opioid requirements during and after surgery, prolong neuromuscular block and all patient were hemodynamically stable.
