technique. Ten minutes later, the patient became agitated, referring general discomfort, blurred vision, perioral numbness and metallic flavour. She became progressively more lethargic and less responsive to stimulus. She became bradycardic and with high blood pressure. LAST treatment was immediately started according to our hospital’s protocol. After stabilization, she was admitted to anaesthetic post-care unit for surveillance and treatment of eventual complications. The symptoms progressively disappeared and she was discharged on the day after.

Conclusions Despite ultrasound technique may increase safety compared with landmark block technique, the risk of vascular contamination during puncture through microscopic bleeding is a major factor for reported LAST cases after this approach.

Postoperative Delirium: A Surgeon’s Dilemma

R Khandelwal*, AHPGIC, Cuttack, India

10.1136/rapm-2021-ESRA.29

Background and Aims Iatrogenic meningitis following spinal anaesthesia is rare but serious complication which can perplex the surgeon. The diagnosis of iatrogenic meningitis is difficult in the usual setting. As, all post – operative complications are directly targeted at the surgeon, this one too puts the surgeon in a challenging situation. It at times becomes difficult to explain to the relatives the cause of the patient’s condition.

Methods A 49 year female attended the OPD for complain of post menopausal bleeding since 3 months. Her ultrasound report showed an endometrial thickness of 11 mm with slightly enlarged uterus. An office endometrial biopsy (EB) was done. The EB report was suggestive of simple hyperplasia without any atypia. So, considering her symptoms she was planned for vaginal hysterectomy and, pre-anesthetic clearance was obtained. Eight hours following the surgery, the patient was found to be somnolent and confused.

Results Post-spinal meningitis should be considered in differential diagnosis of patients having post-spinal headache, convulsions and changes in mental status. Its etiology includes failure of aseptic techniques, presence of asymptomatic bacteremia, contamination during puncture through microscopic bleeding and possibility of aseptic chemical meningitis.

Conclusions The diagnosis of post-spinal aseptic meningitis caused probably by the hyperbaric bupivacaine injected in the subarachnoid space was made and this should alert surgeon and anesthesiologist about the possible but rare consequences of spinal anesthesia. We believe that the rarity of this complication necessitates health care providers all over the world to share such cases for early diagnosis and for instituting proper care to such patients.

Regional Anaesthesia Management of a Trauma Patient with Upper and Lower Extremity Injuries

M Georgiou*, E Xynis, S Coppens. 1 Nicosia General Hospital, Nicosia, Cyprus; 2 University Hospitals, Leuven, Belgium

10.1136/rapm-2021-ESRA.31

Background and Aims Regional anaesthesia remains an essential part of perioperative care. Along with excellent pain control it reduces opioid need while diminishing stress response. Despite these obvious advantages, regional anaesthesia is often underutilized in trauma patients. This is due to time management issues as well as fear of complications like masking of compartment syndrome and nerve damage. We present a case of multiple trauma patient with upper and lower extremity injuries managed solely with regional anaesthesia and sedation.

Methods 47-year-old male 75 kg presented to the emergency department after a motorcycle accident with fractures of the left femur, pelvis, right tibia and left wrist. Further radiological results were negative. The patient showed signs of upper respiratory tract infection. The perioperative plan incorporating regional anaesthesia was consented.

Results Combined spinal epidural anaesthesia was initiated for surgery of lower extremity injuries. Additionally, an infraclassacular block was performed for anaesthesia of wrist fracture. Sedation with propofol and ketamine aided with protracted operative time. The procedure was further uneventful.

Conclusions Trauma patients are more prone to long term opioid dependence. Therefore sparing opioid use and
